5.1 Introduction

- ▶ `for` repetition statement
- ▶ `do...while` repetition statement
- ▶ `switch` multiple-selection statement
- ▶ `break` statement
- ▶ `continue` statement
- ▶ Logical operators
- ▶ Control statements summary.

5.2 Essentials of Counter-Controlled Repetition

- ▶ Counter-controlled repetition requires
 - a **control variable** (or loop counter)
 - the **initial value** of the control variable
 - the **increment** (or **decrement**) by which the control variable is modified each time through the loop (also known as **each iteration of the loop**)
 - the **loop-continuation condition** that determines if looping should continue.

```

1  // Fig. 5.1: WhileCounter.java
2  // Counter-controlled repetition with the while repetition statement.
3
4  public class WhileCounter
5  {
6      public static void main( String[] args )
7      {
8          int counter = 1; // declare and initialize control variable
9
10         while ( counter <= 10 ) // loop-continuation condition
11         {
12             System.out.printf( "%d ", counter );
13             ++counter; // increment control variable by 1
14         } // end while
15
16         System.out.println(); // output a newline
17     } // end main
18 } // end class WhileCounter

```

Declares and initializes control variable
counter to 1

Loop-continuation condition tests for
count's final value

Initializes gradeCounter to 1;
indicates first grade about to be input

```

1 2 3 4 5 6 7 8 9 10

```

5.3 for Repetition Statement

▶ `for` repetition statement

- Specifies the counter-controlled-repetition details in a single line of code.
- Figure 5.2 reimplements the application of Fig. 5.1 using `for`.

```
1 // Fig. 5.2: ForCounter.java
2 // Counter-controlled repetition with the for repetition statement.
3
4 public class ForCounter
5 {
6     public static void main( String[] args )
7     {
8         // for statement header includes initialization,
9         // loop-continuation condition and increment
10        for ( int counter = 1; counter <= 10; counter++ )
11            System.out.printf( "%d ", counter );
12
13        System.out.println(); // output a newline
14    } // end main
15 } // end class ForCounter
```

for statement's header contains everything you need for counter-controlled repetition

```
1 2 3 4 5 6 7 8 9 10
```

Fig. 5.2 | Counter-controlled repetition with the for repetition statement.

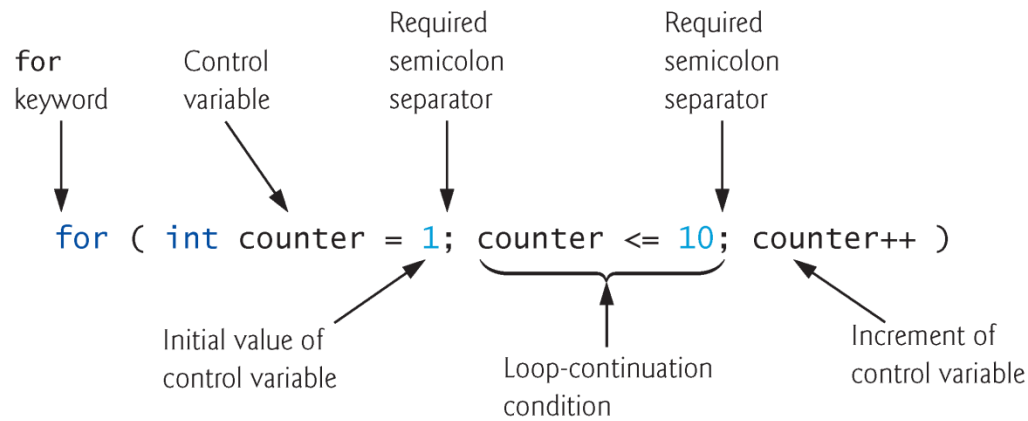

Fig. 5.3 | for statement header components.

5.3 for Repetition Statement (Cont.)

- ▶ The general format of the **for** statement is

```
for ( initialization;  
      loopContinuationCondition; increment )  
    statement
```

- the *initialization* expression names the loop's control variable and optionally provides its initial value
 - *loopContinuationCondition* determines whether the loop should continue executing
 - *increment* modifies the control variable's value (possibly an increment or decrement), so that the loop-continuation condition eventually becomes false.
- ▶ The two semicolons in the **for** header are required.

5.3 for Repetition Statement (Cont.)

- ▶ In most cases, the **for** statement can be represented with an equivalent **while** statement as follows:

```
initialization;
while ( loopContinuationCondition )
{
    statement
    increment;
}
```

- ▶ Typically, **for** statements are used for **counter-controlled repetition** and **while** statements for **sentinel-controlled repetition**.
- ▶ If the *initialization* expression in the **for** header declares the control variable, the control variable can be used **only** in that **for** statement.
- ▶ A variable's **scope** defines where it can be used in a program.
 - A local variable can be used only in the method that declares it and only from the point of declaration through the end of the method.

5.3 for Repetition Statement (Cont.)

- ▶ All three expressions in a **for** header are **optional**.
 - If the *loopContinuationCondition* is omitted, the condition is always true, thus creating an **infinite loop**.
 - You might omit the *initialization* expression if the program initializes the control variable before the loop.
 - You might omit the *increment* if the program calculates it with statements in the loop's body or if no increment is needed.
- ▶ The increment expression in a **for** acts as if it were a standalone statement at the end of the **for**'s body, so

```
counter = counter + 1  
counter += 1  
++counter  
counter++
```

are equivalent increment expressions in a **for** statement.

5.3 for Repetition Statement (Cont.)

- ▶ The initialization, loop-continuation condition and increment can **contain arithmetic expressions**.
- ▶ For example, assume that $x = 2$ and $y = 10$. If x and y are not modified in the body of the loop, the statement
`for (int j = x; j <= 4 * x * y; j += y / x)`
- ▶ is equivalent to the statement
`for (int j = 2; j <= 80; j += 5)`
- ▶ The increment of a **for** statement may be negative, in which case it's a decrement, and the loop counts downward.

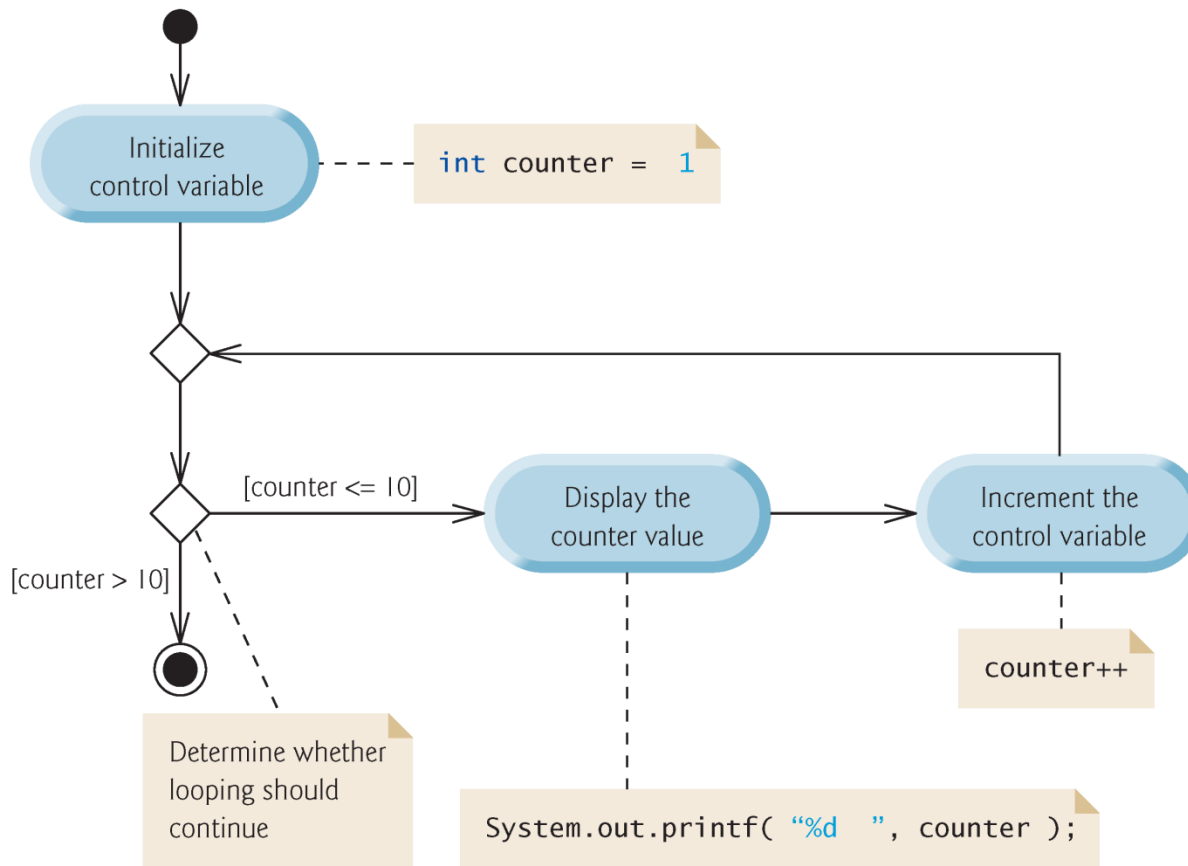

Fig. 5.4 | UML activity diagram for the `for` statement in Fig. 5.2.

5.4 Examples Using the for Statement

- ▶ a) Vary the control variable from 1 to 100 in increments of 1.

```
for ( int i = 1; i <= 100; i++ )
```

- ▶ b) Vary the control variable from 100 to 1 in decrements of 1.

```
for ( int i = 100; i >= 1; i-- )
```

- ▶ c) Vary the control variable from 7 to 77 in increments of 7.

```
for ( int i = 7; i <= 77; i += 7 )
```

5.4 Examples Using the for Statement (Cont.)

- ▶ d) Vary the control variable from 20 to 2 in decrements of 2.

```
for ( int i = 20; i >= 2; i -= 2 )
```

- ▶ e) Vary the control variable over the values 2, 5, 8, 11, 14, 17, 20.

```
for ( int i = 2; i <= 20; i += 3 )
```

- ▶ f) Vary the control variable over the values 99, 88, 77, 66, 55, 44, 33, 22, 11, 0.

```
for ( int i = 99; i >= 0; i -= 11 )
```

```
1 // Fig. 5.5: Sum.java
2 // Summing integers with the for statement.
3
4 public class Sum
5 {
6     public static void main( String[] args )
7     {
8         int total = 0; // initialize total
9
10        // total even integers from 2 through 20
11        for ( int number = 2; number <= 20; number += 2 )
12            total += number;
13
14        System.out.printf( "Sum is %d\n", total ); // display results
15    } // end main
16 } // end class Sum
```

Note that the increment in this loop is 2, since we wish to total only the even integers

Sum is 110

Fig. 5.5 | Summing the even integers from 2 to 20 with the for statement.

5.4 Examples Using the for Statement (Cont.)

- ▶ Compound interest application
- ▶ *A person invests \$1000 in a savings account yielding 5% interest. Assuming that all the interest is left on deposit, calculate and print the amount of money in the account at the end of each year for 10 years. Use the following formula to determine the amounts:*

$$a = p (1 + r)^n$$

where

p is the original amount invested (i.e., the principal)

r is the annual interest rate (e.g., use 0.05 for 5%)

n is the number of years

a is the amount on deposit at the end of the nth year.

5.4 Examples Using the for Statement (Cont.)

- ▶ The solution to this problem (Fig. 5.6) involves a loop that performs the indicated calculation for each of the 10 years the money remains on deposit.
- ▶ Java treats floating-point constants like `1000.0` and `0.05` as type `double`.
- ▶ Java treats whole-number constants like `7` and `-22` as type `int`.

```
1 // Fig. 5.6: Interest.java
2 // Compound-interest calculations with for.
3
4 public class Interest
5 {
6     public static void main( String[] args )
7     {
8         double amount; // amount on deposit at end of each year
9         double principal = 1000.0; // initial amount before interest
10        double rate = 0.05; // interest rate
11
12        // display headers
13        System.out.printf( "%s%20s\n", "Year", "Amount on deposit" );
14
15        // calculate amount on deposit for each of ten years
16        for ( int year = 1; year <= 10; year++ )
17        {
18            // calculate new amount for specified year
19            amount = principal * Math.pow( 1.0 + rate, year );
20        }
```

Java treats floating-point literals as double values

Uses static method `Math.pow` to help calculate the amount on deposit

Fig. 5.6 | Compound-interest calculations with for. (Part 1 of 2.)

```
21         // display the year and the amount
22         System.out.printf( "%4d%,20.2f\n", year, amount );
23     } // end for
24 } // end main
25 } // end class Interest
```

Comma in format specifier indicates that large numbers should be displayed with thousands separators

| Year | Amount on deposit |
|------|-------------------|
| 1 | 1,050.00 |
| 2 | 1,102.50 |
| 3 | 1,157.63 |
| 4 | 1,215.51 |
| 5 | 1,276.28 |
| 6 | 1,340.10 |
| 7 | 1,407.10 |
| 8 | 1,477.46 |
| 9 | 1,551.33 |
| 10 | 1,628.89 |

Fig. 5.6 | Compound-interest calculations with `for`. (Part 2 of 2.)

5.4 Examples Using the for Statement (Cont.)

- ▶ In the format specifier `%20s`, the integer 20 between the % and the conversion character `s` indicates that the value output should be displayed with a **field width** of 20—that is, `printf` displays the value with at least 20 character positions.
- ▶ If the value to be output is less than 20 character positions wide, the value is **right justified** in the field by default.
- ▶ If the `year` value to be output has more characters than the field width, the field width would be extended to the right to accommodate the entire value.
- ▶ To indicate that values should be output **left justified**, precede the field width with the **minus sign (–) formatting flag** (e.g., `%-20s`).

5.4 Examples Using the for Statement (Cont.)

- ▶ Java does not include an exponentiation operator—`Math` class `static` method `pow` can be used for raising a value to a power.
- ▶ You can call a `static` method by specifying the class name followed by a dot (`.`) and the method name, as in
 - `ClassName.methodName(arguments)`
- ▶ `Math.pow(x, y)` calculates the value of `x` raised to the `yth` power. The method receives two `double` arguments and returns a `double` value.

5.4 Examples Using the for Statement (Cont.)

- ▶ In the format specifier `%,20.2f`, the **comma (,)** **formatting flag** indicates that the floating-point value should be output with a **grouping separator**.
- ▶ Separator is specific to the user's locale (i.e., country).
- ▶ In the United States, the number will be output using commas to separate every three digits and a decimal point to separate the fractional part of the number, as in 1,234.45.
- ▶ The number 20 in the format specification indicates that the value should be output right justified in a field width of 20 characters.
- ▶ The `.2` specifies the formatted number's precision—in this case, the number is rounded to the nearest hundredth and output with two digits to the right of the decimal point.

5.5 do...while Repetition Statement

- ▶ The **do...while repetition statement** is similar to the **while** statement.
- ▶ In the **while**, the program tests the loop-continuation condition at the beginning of the loop, **before** executing the loop's body; if the condition is false, the body never executes.
- ▶ The **do...while** statement tests the loop-continuation condition *after executing the loop's body*; therefore, the body always executes **at least once**.
- ▶ When a **do...while** statement terminates, execution continues with the next statement in sequence.

```
1 // Fig. 5.7: DoWhileTest.java
2 // do...while repetition statement.
3
4 public class DoWhileTest
5 {
6     public static void main( String[] args )
7     {
8         int counter = 1; // initialize counter
9
10        do
11        {
12            System.out.printf( "%d ", counter );
13            ++counter;
14        } while ( counter <= 10 ); // end do...while
15
16        System.out.println(); // outputs a newline
17    } // end main
18 } // end class DoWhileTest
```

Condition tested at end of loop, so loop always executes at least once

```
1 2 3 4 5 6 7 8 9 10
```

Fig. 5.7 | do...while repetition statement.

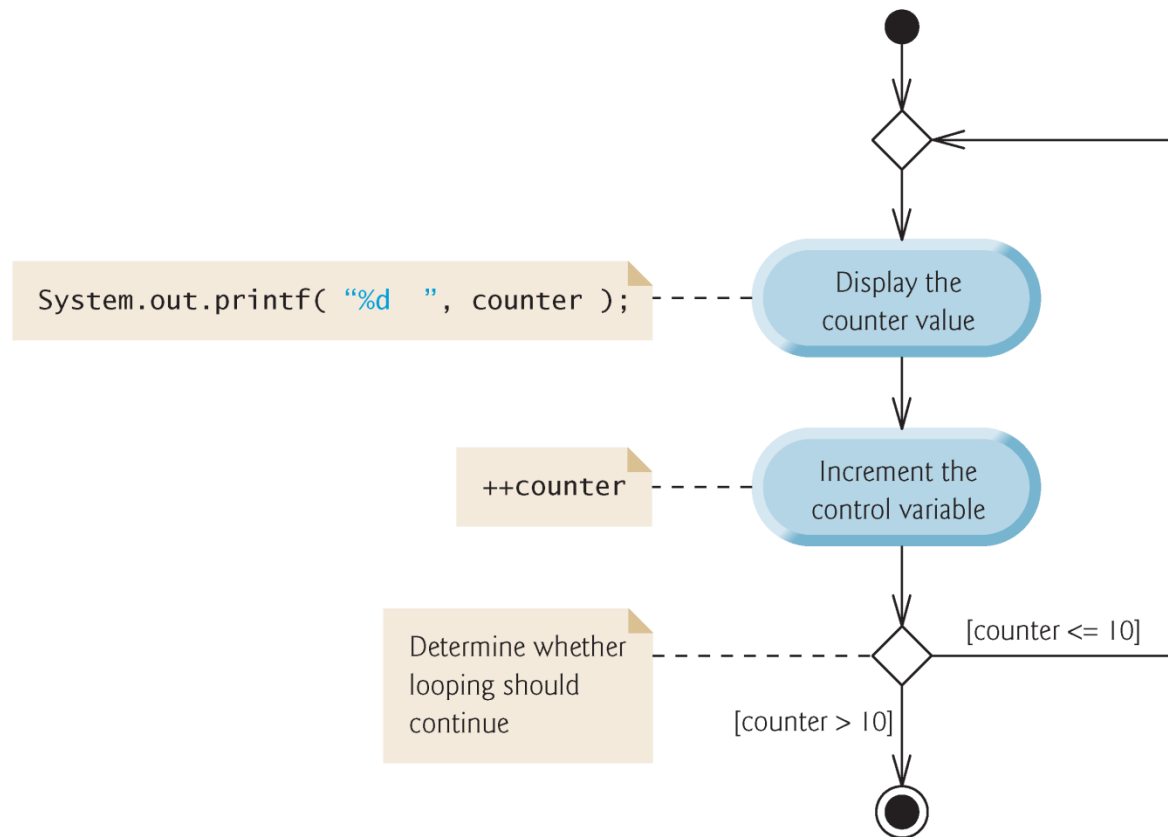

Fig. 5.8 | do...while repetition statement UML activity diagram.

5.5 do...while Repetition Statement (Cont.)

- ▶ Braces are not required in the do...while repetition statement if there's **only one statement** in the body.
- ▶ Most programmers include the braces, to avoid confusion between the while and do...while statements.
- ▶ Thus, the do...while statement with one body statement is usually written as follows:

```
• do
{
    statement
} while ( condition );
```

5.6 switch Multiple-Selection Statement

- ▶ `switch` **multiple-selection statement** performs different actions based on the possible values of a **constant integral expression** of type `byte`, `short`, `int` or `char`.

```
1 // Fig. 5.9: GradeBook.java
2 // GradeBook class uses switch statement to count letter grades.
3 import java.util.Scanner; // program uses class Scanner
4
5 public class GradeBook
6 {
7     private String courseName; // name of course this GradeBook represents
8     // int instance variables are initialized to 0 by default
9     private int total; // sum of grades
10    private int gradeCounter; // number of grades entered
11    private int aCount; // count of A grades
12    private int bCount; // count of B grades
13    private int cCount; // count of C grades
14    private int dCount; // count of D grades
15    private int fCount; // count of F grades
16
17    // constructor initializes courseName;
18    public GradeBook( String name )
19    {
20        courseName = name; // initializes courseName
21    } // end constructor
22
```

No need to initialize these totals and counters to 0, though many programmers consider this a good programming practice

```
23 // method to set the course name
24 public void setCourseName( String name )
25 {
26     courseName = name; // store the course name
27 } // end method setCourseName
28
29 // method to retrieve the course name

31 {
32     return courseName;
33 } // end method getCourseName
34
35 // display a welcome message to the GradeBook user
36 public void displayMessage()
37 {
38     // getCourseName gets the name of the course
39     System.out.printf( "Welcome to the grade book for\n%s!\n\n",
40         getCourseName() );
41 } // end method displayMessage

47
48     int grade; // grade entered by user
49
50     System.out.printf( "%s\n%s\n  %s\n  %s\n",
51         "Enter the integer grades in the range 0-100.",
52         "Type the end-of-file indicator to terminate input:",
53         "On UNIX/Linux/Mac OS X type <Ctrl> d then press Enter",
54         "On Windows type <Ctrl> z then press Enter" );
55
56     // loop until user enters the end-of-file indicator
57     while ( input.hasNext() )
58     {
59         grade = input.nextInt(); // read grade
60         total += grade; // add grade to total
61         ++gradeCounter; // increment number of grades

```
67
68 // add 1 to appropriate counter for specified grade

70 {
71     // determine which grade was entered
72     switch ( grade / 10 )
73     {
74         case 9: // grade was between 90
75         case 10: // and 100, inclusive
76             ++aCount; // increment aCount
77             break; // necessary to exit switch
78
79         case 8: // grade was between 80 and 89
80             ++bCount; // increment bCount
81             break; // exit switch
82
83         case 7: // grade was between 70 and 79

88             ++dCount; // increment dCount

109         System.out.printf( "Total of the %d grades entered is %d\n",
110             gradeCounter, total );

5.6 switch Multiple-Selection Statement (Cont.)

- ▶ Scanner method `hasNext` determine whether there is more data to input. This method returns the `boolean` value `true` if there is more data; otherwise, it returns `false`.
- ▶ As long as the end-of-file indicator has not been typed, method `hasNext` will return `true`.

5.6 `switch` Multiple-Selection Statement (Cont.)

- ▶ The `switch` statement consists of a block that contains a sequence of `case labels` and an optional `default case`.
- ▶ The program evaluates the `controlling expression` in the parentheses following keyword `switch`.
- ▶ The program compares the controlling expression's value (which must evaluate to an integral value of type `byte`, `char`, `short` or `int`) with each `case` label.
- ▶ If a match occurs, the program executes that `case`'s statements.
- ▶ The `break statement` causes program control to proceed with the `first statement after` the `switch`.

5.6 `switch` Multiple-Selection Statement (Cont.)

- ▶ `switch` does not provide a mechanism for testing ranges of values—every value must be listed in a separate `case` label.
- ▶ Note that each `case` can have multiple statements.
- ▶ `switch` differs from other control statements in that it **does not require braces** around multiple statements in a `case`.
- ▶ Without `break`, the statements for a matching case and subsequent cases execute until a `break` or the end of the `switch` is encountered. This is called “**falling through.**”
- ▶ If no match occurs between the controlling expression’s value and a `case` label, the **default** case executes.
- ▶ If no match occurs and there is no **default** case, program control **simply continues** with the first statement after the `switch`.

5.7 break and continue Statements

- ▶ The **break** statement, when executed in a **while**, **for**, **do...while** or **switch**, causes **immediate exit** from that statement.
- ▶ Execution continues with the first statement after the control statement.
- ▶ Common uses of the **break** statement are to **escape early** from a loop or to skip the remainder of a **switch**.

```
1 // Fig. 5.12: BreakTest.java
2 // break statement exiting a for statement.
3 public class BreakTest
4 {
5     public static void main( String[] args )
6     {
7         int count; // control variable also used after loop terminates
8
9         for ( count = 1; count <= 10; count++ ) // loop 10 times
10        {
11            if ( count == 5 ) // if count is 5,
12                break; // terminate loop
13
14            System.out.printf( "%d ", count );
15        } // end for
16
17        System.out.printf( "\nBroke out of loop at count = %d\n", count );
18    } // end main
19 } // end class BreakTest
```

Terminates the loop immediately and
program control continues at line 17

```
1 2 3 4
Broke out of loop at count = 5
```

Fig. 5.12 | break statement exiting a for statement.

5.7 break and continue Statements (Cont.)

- ▶ The `continue` statement, when executed in a `while`, `for` or `do...while`, skips the remaining statements in the loop body and **proceeds with the next iteration of the loop**.
- ▶ In `while` and `do...while` statements, the program evaluates the loop-continuation test immediately after the `continue` statement executes.
- ▶ In a `for` statement, the increment expression executes, then the program evaluates the loop-continuation test.

```
1 // Fig. 5.13: ContinueTest.java
2 // continue statement terminating an iteration of a for statement.
3 public class ContinueTest
4 {
5     public static void main( String[] args )
6     {
7         for ( int count = 1; count <= 10; count++ ) // loop 10 times
8         {
9             if ( count == 5 ) // if count is 5,
10                continue; // skip remaining code in loop
11
12             System.out.printf( "%d ", count );
13         } // end for
14
15         System.out.println( "\nUsed continue to skip printing 5" );
16     } // end main
17 } // end class ContinueTest
```

Terminates current iteration of loop
and proceeds to increment

```
1 2 3 4 6 7 8 9 10
Used continue to skip printing 5
```

5.8 Logical Operators

- ▶ Java's **logical operators** enable you to form more complex conditions by combining simple conditions.
- ▶ The logical operators are
 - `&&` (conditional AND)
 - `||` (conditional OR)
 - `&` (boolean logical AND)
 - `|` (boolean logical inclusive OR)
 - `^` (boolean logical exclusive OR)
 - `!` (logical NOT).
- ▶ [*Note:* The `&`, `|` and `^` operators are also bitwise operators when they are applied to integral operands.]

5.8 Logical Operators (Cont.)

- ▶ The **&& (conditional AND)** operator ensures that two conditions are *both true* before choosing a certain path of execution.
- ▶ The table in Fig. 5.14 summarizes the **&&** operator. The table shows all four possible combinations of **false** and **true** values for *expression1* and *expression2*.
- ▶ Such tables are called **truth tables**. Java evaluates to **false** or **true** all expressions that include relational operators, equality operators or logical operators.

| expression1 | expression2 | expression1 && expression2 |
|-------------|-------------|----------------------------|
| false | false | false |
| false | true | false |
| true | false | false |
| true | true | true |

Fig. 5.14 | && (conditional AND) operator truth table.

5.8 Logical Operators (Cont.)

- ▶ The `||` (**conditional OR**) operator ensures that *either or both* of two conditions are true before choosing a certain path of execution.
- ▶ Figure 5.15 is a truth table for operator conditional OR (`||`).
- ▶ Operator `&&` has a higher precedence than operator `||`.
- ▶ Both operators associate from left to right.

| expression1 | expression2 | expression1 expression2 |
|-------------|-------------|----------------------------|
| false | false | false |
| false | true | true |
| true | false | true |
| true | true | true |

Fig. 5.15 | || (conditional OR) operator truth table.

5.8 Logical Operators (Cont.)

- ▶ The **!** (**logical NOT**, also called **logical negation** or **logical complement**) operator “reverses” the meaning of a condition.
- ▶ The logical negation operator is a unary operator that has only a single condition as an operand.
- ▶ The logical negation operator is placed before a condition to choose a path of execution if the original condition (without the logical negation operator) is **false**.
- ▶ In most cases, you can avoid using logical negation by expressing the condition differently with an appropriate relational or equality operator.
- ▶ Figure 5.17 is a truth table for the logical negation operator.

| expression | !expression |
|------------|-------------|
| false | true |
| true | false |

Fig. 5.17 | ! (logical negation, or logical NOT) operator truth table.

5.8 Logical Operators (Cont.)

- ▶ Figure 5.18 produces the truth tables discussed in this section.
- ▶ The `%b` **format specifier** displays the word “true” or the word “false” based on a `boolean` expression’s value.

```

6     public static void main( String[] args )
7     {
8         // create truth table for && (conditional AND) operator
9         System.out.printf( "%s\n%s: %b\n%s: %b\n%s: %b\n\n",
10             "Conditional AND (&&)", "false && false", ( false && false ),

17             "Conditional OR (||)", "false || false", ( false || false ),
18             "false || true", ( false || true ),
19             "true || false", ( true || false ),
20             "true || true", ( true || true ) );

5.9 Structured Programming Summary

- ▶ Figure 5.20 uses UML activity diagrams to summarize Java's control statements.
- ▶ Java includes only single-entry/single-exit control statements—there is only one way to enter and only one way to exit each control statement.
- ▶ Connecting control statements in sequence to form structured programs is simple. The final state of one control statement is connected to the initial state of the next—that is, the control statements are placed one after another in a program in sequence. We call this control-statement stacking.
- ▶ The rules for forming structured programs also allow for control statements to be nested.
